Introduction to Particle Swarm Optimization

Rajib Kumar Bhattacharjya Department of Civil Engineering Indian Institute of Technology Guwahati

Inspired by social behavior of bird flocking and fish schooling

Suppose a group of birds is searching food in an area

Only one piece of food is available

Birds do not have any knowledge about the location of the food

But they know how far the food is from their present location

So what is the best strategy to locate the food?

United we stand

The best strategy is to follow the bird nearest to the food

Current position

A flying birds has a position and a velocity at any time *t*

In search of food, the bird changes his position by adjusting the velocity

The changes the velocity based on his past experience and also the feedbacks received from his neighbour This searching process can be artificially simulated for solving non-linear optimization problem

So this is a population based stochastic optimization technique inspired by social behaviour of bird flocking or fish schooling

Each solution is considered as bird, called particle

All the particles have a fitness value. The fitness values can be calculated using objective function

All the particles preserved their individual best performance

They also know the best performance of their group

They adjust their velocity considering their best performance and also considering the best performance of the best particle

Particle Swarm Algorithm Inertia effect Initialize particles Evaluate fitness of each particles Local search, personal influence Modify velocities based on previous best and global best positions Global search, Social influence Next iteration Terminate criteria **STOP** Velocity is updated $V_{i+1} = \omega V_i + C_1 * rand() * (PB_i - X_i) + C_2 * rand() * (GB_i - X_i)$ Position is updated C_1 and C_2 are the learning factor $X_{i+1} = X_i + V_{i+1}$ ω is the inertia weight
